

Behavioral skewness notation

Compare real human trajectories selected by each persona source to a within-game uniform human baseline.

Human baseline	$P_g(i) = 1/n_g$	uniform over observed players in game g
LLM-persona match	$Q_{gs}(i) = \text{Avg}_a r_{gasi}$	average top-3 probabilities across personas
Plotted skew	$\tilde{\delta}_{sl} = \frac{1}{\sigma_l^P} \text{Avg}_g \{E_{Q_{gs}}[x_\ell] - E_{P_g}[x_\ell]\}$	SD-standardized feature difference

x_{gil} = behavior feature ℓ for player i in game g ; $r_{gasi} = 0$ for unlisted top-3 players. Values near 0 match the human baseline; positive/negative values indicate over-/under-selection.
